1.Chronic inflammatory response

Basis for judgment:Elevated NSH# suggests chronic inflammation or stress, commonly seen in chronic infections or inflammatory diseases, accompanied by fever or localized swelling.

2.No significant hematological abnormalities

Basis for judgment:All blood cell parameters are Within Normal Range, with no signs of anemia, infection, or inflammation, suggesting the body's blood system is basically Within Normal Range.

Low Normal High

NSH# 0.51 10³/uL ↑ (0.00-0.40)
-Clinical indication:Neutrophil right shift, commonly seen in Vitamin B 12 or folic acid deficiency, use of antimetabolites, long-term antibiotic or hormone use, metabolic issues, chronic inflammation, etc. A right shift is a sign of declining bone marrow hematopoietic function, often caused by severe systemic exhaustion in serious cases.
-Basis for judgment:Vitamin B 12 or folic acid deficiency affects all rapidly dividing cells, leading to DNA synthesis disorders → delayed nuclear development resulting in a right shift. During the recovery phase of inflammation, a transient neutrophil right shift often occurs. Severe right shift suggests bone marrow failure; in critical illness, exhaustion of hematopoietic function and reduced resistance indicate a poor prognosis;

Possible diseases and basis for inference

Chronic bacterial infection High
Elevated NSH# is closely related to persistent bacterial infections, seen in chronic pyoderma, urinary tract infections, etc.
Chronic inflammatory diseases Medium
Such as chronic pancreatitis or chronic arthritis, which can lead to delayed neutrophil maturation and increased release
Stress-related reaction Low
Long-term environmental stress or psychological pressure can also cause hypersegmented neutrophilia, but organic lesions must be ruled out
